

### **Remarks**

Claims 19-22, 24-28, 30-36 and 50-98 are in the application, of which claims 19, 36, 62, 65, and 66 are in independent form. Claims 62-98 are allowed. Dependent claims 99-113 are added, without introducing new matter.

### ***Telephone Interview Summary***

The undersigned wishes to thank the examiner for the telephone interview on June 29, 2006, during which the examiner agreed to allow claims 1-60 in view of the amendments to claims 19, 21, 22, 27-34, 36, 58-60 and the remarks set forth below. The examiner also noted that claim 61 would be allowable if amended to correct for a lack of antecedent basis for the term "a source of data", which informality was inadvertently introduced by the proposed amendments to claim 19. Accordingly, Applicant amends claim 61 to delete reference to "the source of data", without adding new matter. Applicant believes claim 61 is allowable as amended.

During the interview, the examiner also discussed the scope of claim 62 with the undersigned. Specifically, the examiner noted that claim 62 does not necessarily require that the "financial market data" recited in the second paragraph of claim 62 concern the "financial market" of the first paragraph and to which the bet parameters relate. Applicant believes that no amendment to claim 62 is warranted, finding support for claim 62 in the original specification at page 8, lines 15-24, and at page 9, line 30 to page 10, line 14 (substitute specification at page 8, lines 20-29 and page 10, lines 3-19).

### ***Amendments to the Specification***

Without adding new matter, the specification is amended to clarify the disclosure and to avoid language that may unintentionally affect the proper interpretation of the claims.

### ***Rejections Under 35 U.S.C. § 112***

Claims 19-22, 24-37 and 50-60 stand rejected under 35 U.S.C. § 112, second paragraph, as being incomplete for omitting essential steps. In particular, the Office action states at page 2 that "connectivity of the user terminal to the central processing machine and

the source of the data concerning the financial market to the processing machine” are omitted. In response, applicant amends claim 19 to specify that the central processing machine is in communication with a data feed to a source of data concerning a financial market and to specify that the user terminal is in communication with the central processing machine.

With respect to claim 21, the Office action indicates that there is no antecedent for the placing of the bet. The Office action also states that the limitation “deducting payment from the user” is vague and unclear, and “no method step(s) involving the user account is provided to facilitate deducting payment”. In response, applicant amends claim 21 to add the limitation “receiving an authorization from the user to place the bet” and to change “deducting payment” to “receiving a payment”, it being intended that receipt of payment is not limited to payment submitted via a particular means or at a particular time. For example, payment may be received and credited to a user’s account later or earlier than the account is debited, upon placing a bet. The manner of accounting being a ministerial act not forming an essential element of claim 21. Applicant believes the amendments to claim 21 address the vagueness issues raised in the Office action without unnecessarily limiting the claim to particular accounting steps.

With respect to claim 22, the Office action states that the limitations of “varying an account of the user” renders the claim indefinite because the claim fails to specify a specific property of the account. In response, applicant amends claim 22 to change “varying” to “crediting”, and thereby specify that a credit is applied to the account to increase its balance. The Office action also states that the limitation in claim 22 of “financial market satisfying the parameters of the bet” is unclear because the claim fails to specify a specific property of the financial market, such as index prices, volumes, etc. As recognized by the Office action, there are many aspects of the financial market that may be the subject of a bet within the scope of the claimed method. Examples of such aspects include index prices, volumes, option quotes, interest rates, currency exchange rates, dividend yields, and market prices for particular stocks or indices, and carrying costs for commodities, such as the cost of insurance, storage, or delivery. See Specification at pages 4, 7, 8. Certain such “aspects” are claimed in dependent claims 55-57. Moreover, claim 19 recognizes without limiting to a specific market property that a fixed-odds bet may be placed on “an aspect” of a financial market. Therefore, applicant is amending claim 22 only to specify that it is the fluctuation of said aspect of the

financial market on which the user is betting which must satisfy the parameters of the bet. Applicant believes these amendments to claim 22 sufficiently clarify the scope of the claim so as to overcome the grounds for rejection.

Claims 27-29 and 32 are rejected because the role of the steps in the claims as a whole are unclear because an effect of the steps on the calculation of fixed odds is not recited. Applicant traverses and requests reconsideration in view of amendments to the claims. Contrary to the Office action, applicant asserts that the absence of a recited effect of the method steps of claims 27 and 28 does not render the claims unclear. In fact, if claims 27 or 28 were to positively recite an effect of the claimed checking steps, it would be to prevent the calculating step of claim 19 – which would result in a claim scope inconsistent with base claim 19. Nevertheless, claims 27 and 28 are amended to establish the order of the recited steps in the context of the claim as a whole. Applicant asserts that claims 27 and 28 are allowable as amended.

Claim 29 is cancelled and its subject matter clarified and added to dependent claims 30 and 31.

Claim 32 is amended to affirmatively recite the storing of information relating to previously placed bets.

Claims 33 and 34 are amended to clarify the scope of the claims, without adding new matter.

Claim 36, 37, 50, and 51 are rejected as allegedly lacking antecedent basis for “the data obtained from the data feed”. This rejection is unclear, as “the data”, “the data feed” and “obtaining data” via the data feed are all recited in claim 36. Applicant nevertheless amends claim 36 to specify that the central processing machine is “in communication with a data feed”, and that the data concerning the financial market is obtained via the data feed.

### ***Rejection Under 35 U.S.C. § 101***

Claims 36, 50 and 51 are rejected as claiming a computer program *per se*, which the Office action alleges is not statutory subject matter. Applicant disagrees insofar as the claim impliedly recites a thing (computer program) which is widely understood as being operable only on a computer (a statutory machine). See AT&T v. Excel Communications, Inc., 172 F.3d 1352, 50 USPQ2d 1447 (Fed. Cir. 1999). Nevertheless, to expedite allowance, claim 36

is amended to incorporate the limitation of claim 37 requiring the computer program to be “embodied on a computer readable medium”. Claim 37 is therefore cancelled.

#### ***Other Amendments***

Claims 58-61 are amended for consistency with changes in claim 19.

Claim 65 is amended to correct an inadvertent drafting error, without adding new matter or changing the intended scope of the claim.

To obtain patent coverage to which Applicant is entitled, this Amendment adds dependent claims 99-113 directed to a fixed-odds betting system, without introducing new matter.

#### ***Conclusion***

Applicant asserts that the claims, as amended, are in condition for allowance and earnestly solicits the same. In the event that any further issues are identified, the examiner is invited to contact the undersigned attorney by telephone.

Payment in the amount of \$300.00 for 12 additional total excess claims is submitted herewith. The Commissioner is authorized to charge any additional fees required in connection with the filing of this response, or credit overpayment, to Deposit Account No. 19-4455.

Respectfully submitted,

## **BETTING SYSTEM AND METHOD**

### **Related Applications**

This application claims priority from European Patent Application No. 00302530.1, filed March 28, 2000, and U.K. Patent Application No. 0010270.7, filed April 27, 2000.

### **Field of the Invention**

~~This invention~~ The present disclosure relates to a betting system and method for buying and selling of fixed-odds financial bets, ~~and in particular to a system by which a user at a remote user terminal may buy and sell fixed-odds financial bets in real time over the Internet.~~

### **Background of the Invention**

Although betting in many diverse forms has been in existence for thousands of years, the concept of a bet on the future performance of one or more financial market indicators is a relatively recent one. Such a bet may take one of two forms, as will be described.

The first form of such a bet (the "spread bet") is one which, if won by the making of a correct prediction, pays out a sum proportional to the market fluctuation. For instance, a speculator may bet that a given stock will fall within a set period of time, and, if this prediction is correct, may receive winnings in direct proportion to the amount by which the stock has fallen in that period of time.

The other form that such a bet may take is known as the "digital option". Digital bets are of the same form as a traditional sporting bet in that the speculator predicts a certain event and receives either a fixed sum of winnings (if that event does occur) or no winnings (if the event does not occur). For instance, a speculator may bet that a certain

stock index will rise to a certain level by a certain time. If the named index does reach this level, the speculator wins an agreed amount of money irrespective of any amount by which the index has exceeded the predicted level. It is this type of bet that is known as a "fixed odds" bet.

However, problems face the individual investor who wishes to place bets on the financial markets. The wide universe of financial instruments and derivatives products is typically available only to professional investors who have the financial resources and know-how to access these products.

Problems also face the bookmaker who wishes to offer financial bets to the private investor. These include the fact that financial bookmaking is labor-intensive, with skilled staff being required constantly to adapt the odds offered on an immense variety of possible bets to market conditions that are changing on a minute-by-minute basis.

The average size of a bet placed by an individual customer will, in general, be very small compared to the average size of a typical stock market direct investment. The potential profit to the bookmaker from such a small investment will therefore be too small for it to be economically viable to employ skilled staff to calculate the odds to offer to individual speculators sufficiently quickly.

A further problem facing bookmakers is that it is very difficult to accurately price complicated or unusual bets, and bookmakers typically offer only a few standard bets on a few markets.

A need exists for a system and method that alleviates some or all of the above problems, and which enables a bookmaker efficiently to offer a wide range of financial bets to speculators wishing to place relatively small bets.

#### Summary of the Invention

Accordingly, a first aspect of the present invention provides ~~According to a first embodiment, a fixed-odds betting system comprising~~ comprises a user terminal operable to accept parameters, input by a user, relating to a fixed-odds bet on an aspect of a financial market; and a central processing machine having a data feed to a source of data concerning a financial market and means operable to calculate the fixed odds for the bet, based on at least some of the parameters input by the user and the data obtained from the data feed. Advantageously, the user terminal ~~is~~ may be operable to receive and

display the odds calculated by the central processing machine.

Preferably, the data feed to the source of data concerning the financial market comprises at least a data feed to real-time information concerning the financial market. Conveniently, the data feed to the source of data concerning the financial market ~~comprises at least~~ may comprise a data feed to historical data concerning the financial market. Advantageously, the data feed is connected to the source of data concerning the financial market over a first data communications network. Preferably, the first data communications network is the Internet or a leased line. The central processing machine may have at least one other data feed to a source of data concerning one or more other financial markets.

The user terminal and the central processing machine are preferably connected to one another via a second data communications network such as the Internet.

Conveniently, the system ~~may further comprises~~ comprise a payment system for deducting payment for the bet from the user, the mechanism being linked to the central processing machine. The payment system for deducting payment from the user may include an E-cash or credit card payment system.

The system may further comprise an accounting system linked to the central processing machine and a management terminal operable to provide information regarding the operation of the betting system to an administrator thereof.

Advantageously, the parameters for calculating the odds may include one or more of the following: the relevant financial market(s); the amount that the user wishes to bet or the amount that the user wishes to win; and one or more barrier or target levels.

The system may further comprise a storage facility for storing information relating to bets. The central processing machine preferably includes means to retrieve information stored in the storage facility, and provide information to a user relating to a bet previously placed by the user.

Preferably, the central processing machine includes means to calculate a price at which to offer to purchase the previously placed bet from the user and to display the price calculated by the central processing machine.

~~Another aspect of the present invention provides~~ In another embodiment, a method of operating a fixed-odds betting system, ~~comprising the steps of: providing~~

including a central processing machine in communication with a data feed to a source of data concerning a financial market, and a user terminal in communication with the central processing machine, comprises ~~operable to accept-accepting from a user~~ parameters relating to a fixed-odds bet on an aspect of a financial market ~~from a user;~~ receiving one or more ~~of the parameters from the user relating to a fixed-odds bet on an aspect of a financial market at the central processing machine;~~ providing a central processing machine; ~~providing a data feed to a source of data concerning a financial market;~~ obtaining data concerning a ~~the~~ financial market via the data feed; and the central processing machine calculating a fixed-odds price for the bet based on at least one of the parameters input by the user and the data obtained from the data feed.

The method may further comprise the steps of displaying the calculated odds to the user and deducting ~~or receiving~~ payment from the user for placing the bet.

Preferably, the step of receiving one or more parameters from the user includes the step of receiving information relating to one or more of the following: the relevant financial market; the amount that the user wishes to win or the amount that the user wishes to bet; and one or more barrier or target levels.

The step of obtaining data concerning the financial market may include the step of obtaining real-time data relating to one or more of the following: market prices; option quotes; interest rates and dividend yields.

The step of obtaining data concerning a financial market may include the steps of obtaining historical data relating to market prices.

Preferably, the step of calculating the fixed-odds price comprises the step of calculating an estimate of the future volatility of the financial market.

Conveniently, the method may further comprise the steps of checking the parameters input by the user for logical inconsistencies therebetween and checking the opening times of the financial market.

Preferably, the method further comprises the step of providing at least one other data feed to a source of data concerning one or more other financial markets.

Conveniently, the step of receiving parameters from the user preferably includes the step of receiving parameters relating to an aspect of the one or more other financial markets.

Advantageously, the step of calculating the fixed-odds price for the bet

preferably includes the step of calculating a correlation matrix containing information concerning the financial market and the one or more other financial markets.

Preferably, the system further comprises the step of providing a storage facility, accessible by the central processing machine, for storing information relating to bets.

Conveniently, the step of calculating odds includes the step of calculating a hedging factor based on information concerning previously placed bets obtained from the storage facility. The method may further comprise the steps of: (1) calculating, at the central processing machine, a price at which to offer to buy a previously placed bet from the user; and providing the price to the user via the user terminal.

~~A further aspect of the present invention provides~~ In yet another embodiment, a computer program comprising ~~comprises~~ computer program code means adapted to: receive one or more parameters from a user relating to a fixed-odds bet on an aspect of a financial market; obtain data concerning a financial market via a data feed; and calculate a fixed-odds price for the bet based on at least one of the parameters input by the user and the data obtained from the data feed.

~~Another aspect of the present invention provides a~~ The computer program as above may be embodied on a computer readable medium or otherwise operable on a computer.

~~A further aspect of the present invention provides~~ In still another embodiment, a central processing machine having a data feed to a source of data concerning a financial market, and being is operable to calculate fixed odds, based on parameters input by a user and data obtained from the data feed.

Conveniently, the data feed to the source of data concerning the financial market may comprise a data feed to real-time information concerning the financial market.

Advantageously, the data feed to the source of data concerning the financial market may comprise a data feed to at least historical data concerning the financial market. Preferably, the data feed is connected to the source of data concerning the financial market over a first data communications network such as the Internet or a leased line.

Advantageously, at least one other data feed ~~is preferably~~ may be provided to a source of data concerning one or more other financial markets.

~~Preferably, the~~ The central processing machine may further comprises ~~comprise~~ a

storage facility for storing information relating to bets.

The central processing machine ~~preferably has may also have~~ means to calculate a price at which to offer to purchase a previously placed bet from the user.

Advantageously, the central processing machine may further comprise a management terminal operable to display information regarding the operation of the betting system to an administrator thereof.

~~Additional objects characteristics and advantages of this invention will be~~ apparent from the following detailed description of preferred embodiments thereof which proceeds with reference to the accompanying drawing.

#### **Brief Description of the Drawing**

Fig. 1 shows a schematic layout of the components of a betting system in accordance with a preferred embodiment of the present invention.

#### **Detailed Description of Preferred Embodiments**

With reference to Fig. 1, a central processing machine 1 of a betting system ~~embodying the present invention in accordance with a preferred embodiment~~ comprises a server running a server operating system. A computer program embodying an aspect of the ~~present invention betting system~~ is loaded onto the central processing machine 1, as will be described in greater detail below.

The central processing machine 1 is linked via a first data communications network 2 to a plurality of user terminals 3. Preferably, the first network 2 is the Internet. The user terminals comprise PC's, or other suitable machines, running an appropriate operating system to interface with prospective customers, for instance a Windows or UNIX type operating system.

The central processing machine 1 is further connected via a second data communications network 4 to two data feeds, one of which is a data feed 5 to a source of real-time market information, and the other of which is a data feed 6 to a source of historical market information. Preferably, the second network 4 is the Internet or a leased line. Examples of real-time market quotes data feeds are those provided by financial information providers such as Reuters, Bloomberg, Bridge, DBC, etc. The primary requirement for this data link is that it should be real-time, which is to say that the quotes retrieved via the data link are up-to-the-second real-time market quotes.

The betting system of Fig. 1 further comprises a data storage facility 7,

comprising a file server operable to store information concerning placed, pending and expired bets on one or more disks. The data storage facility is connected to an archival data storage facility 8, which is operable to retain information on a plurality of tapes or other long-term storage media.

The betting system includes an E-cash or credit card payment system 9, which is linked to the central processing machine 1 by a third data communications network 10. An accounting system 11 is also included in the betting system, this accounting system being directly linked to the central processing machine 1.

A management terminal 12 also comprises part of the betting system. This management terminal 12 is linked to the central processing machine 1 via a fourth data communications network 13, which is preferably the Internet.

In operation, an individual user is able to log on to a user terminal 3 for the purpose of placing a fixed-odds financial bet. A user-id and password, provided to the individual by the administrator of the betting system, may be required to do so. In practice, the user terminal 3 may comprise a dedicated terminal in a public betting facility, or may alternatively comprise the user's own PC.

When the user attempts to log on to the betting system at the user terminal 3, the user terminal 3 connects to the central processing machine 1 via the first network 2. If a password is required, the password must be accepted by the central processing machine 1 before the user is allowed to log on to the betting system.

The user is now able to place a fixed-odds financial bet using the betting system. The user terminal 3 presents the user with a suitable interface for doing so, this interface comprising a number of menus or the like through which the user may navigate to glean information or select bet parameters. Bet parameters that the user may select may include, among others: the financial market(s) upon which the bet is to be based (for instance a foreign exchange rate); the amount that the user wishes to bet or the amount that the user wishes to win; or one or more barrier or target levels (relating to market performance) which set a threshold for the financial market parameter being monitored. Once the bet parameters are decided upon by the user, these parameters are submitted to the central processing machine 1 via the first network 2.

The first step performed by the central processing machine 1 upon receipt of the bet parameters from the user terminal 3 is to ascertain whether or not the bet defined by

the bet parameters is within reasonable reach of current market prices. In order to decide whether or not this is the case, the central processing machine 1 gathers information concerning the current market prices from the data feed 5 to the source of real-time market information. If the data derived therefrom indicates that there is no realistic possibility of the market price changing with the rapidity required by the bet, then the central processing machine 1 will reject the bet.

Next, the bet parameters input by the user are checked by the central processing machine 1 for logical inconsistencies, and the bet is rejected if such inconsistencies are found to be present. For instance, if a user has input bet parameters defining a bet that a certain financial index will remain between a high value of 110 and a low value of 120, the central processing machine 1 will determine that the bet is logically inconsistent and reject the bet.

A further step performed by the central processing machine 1 on receipt of a set of bet parameters from user terminal 3 is to check the opening times of the relevant financial markets. The central processing machine 1 has, for this purpose, a link to a source of information containing the opening hours and public holidays of all of the markets upon which bets are offered. If a user is allowed to bet upon the performance of a market during a period for which that market is closed, the user gains an unfair advantage and thus such a bet would be rejected.

Once it has been established by the central processing machine 1 that the bet parameters input by the user define a valid bet, the next step is to determine the real-time raw market values from which to calculate the price of the bet. In order to do this, the central processing machine 1 accesses the data feed 5 to the source of real-time market information. The data derived therefrom may include current market prices, option quotes, interest rate levels, dividend yields (in the case of stocks or stock indices), or carrying costs (i.e., storage, delivery or insurance costs, in the case of commodities). The central processing machine 1 may also access the data feed 6 to the source of historical market information, and the data gathered therefrom may include historical closing prices for the relevant markets.

Once a set of valid bet parameters have been received by the central processing machine 1 and the relevant information has been gathered from the data feeds 5, 6, the central processing machine 1 uses the information to calculate the odds that will be

offered to the user for the bet.

The first step in the process is to calculate the implied volatility of the or each market upon which the bet is based. The volatility of a market is defined as the amount by which the market fluctuates during a given period, and is often defined as the annualized standard deviation of the natural logarithm of the price returns of the daily closing values of the market.

The implied volatility is the market volatility that the listed options market implies for the future, market volatility being a major factor in the determination of the price of an option. If the price of the listed options relating to a given market for a given time period is known, this figure can be reverse-engineered to calculate the future volatility of the market implied by that option price. Various techniques exist for this reverse engineering operation, the most commonly used of which is an algorithm based on the Black and Scholes option pricing model, however the skilled person will realize that any of several alternative algorithms may be used instead.

A standard option pricing model such as the Black and Scholes model assumes that the financial markets follow a log-normal distribution. This assumption does not, however, accurately reflect the market panics (like the 1987 stock market crash), which occur with a higher frequency than would be expected in a purely lognormal distribution. To adjust for the "fatter tails" of the real distribution of market returns, the concept of "volatility smile" is introduced, whereby options with different strike prices trade at different implied volatilities. Options with different expiry dates also trade at different implied volatilities, reflecting different expectations of market volatility over different time periods. Since there will likely not be any option with exactly the same expiry date and target price as the bet, interpolation will be used to arrive at the best estimate of the volatility for the bet.

To calculate the volatility to be used to price the bet, options prices are gathered from the data feed 5 to the real-time source of market information. The implied volatilities of the options with strike prices closest to the barrier or target level of the bet, and with expiry dates closest to the expiry date of the bet, are computed. These implied volatility points are then interpolated to arrive at the implied volatility most appropriate for the expiry date and barrier or target level of the bet (if the bet has several barrier or target levels, the level that will lead to the highest selling price for the bet may

be used). This interpolated implied volatility is used by the central processing machine 1 to calculate the odds for the bet.

It is also necessary for the central processing machine 1 to take into account the growth of the market or markets in question. In order to derive this value, the interest rate and other components of the carrying cost for each market (extracted from the data feed 5 to the real-time source of market information) are required. For stocks or stock indices, the growth of the market is typically approximated as being the interest rate minus the annualized dividend yield. In a similar manner to that described above, the interest rate for an arbitrary time period may be estimated by interpolating between the deposit rates for earlier and later maturities to arrive at an appropriate value. For foreign exchange rates, the growth rate is defined as the difference between the deposit rates in each currency, and for other markets such as commodities, the growth rate incorporates factors such as storage or delivery costs, and insurance fees.

A complex bet may involve predictions on the performances of several different markets, and if such a bet is placed then a correlation matrix for these different markets will need to be computed. Such a correlation matrix is computed by calculating the correlation coefficients of the relevant markets over a period of historical data obtained from the data feed 6 to the source of historical market information. Ideally, this time period is in proportion to the length of the bet.

Once all of the necessary information has been gathered or computed by the central processing machine 1, the central processing machine 1 proceeds to calculate the odds for the bet defined by the bet parameters. There are various ways in which this may be performed for each type of bet that might be placed by the user. Common bets that might be placed include:

- an “up/down” bet that a given market will be above or below a given level on a given date;

- an “expiry range” bet that a given market will be between two given levels on a given date;

- a “rainbow” bet, which is essentially a multi-market expiry range bet;

- a “bullseye” bet that a given market will have an exactly given value on a given date;

- a “one-touch” bet that a given market will touch a given barrier level at some

point before the expiry of the bet;

a “no-touch” bet that a given market will not touch a given barrier level at any point before the expiry of the bet;

a “range” bet that a given market will touch neither of two given barrier levels at any point before the expiry of the bet;

a “double one-touch” bet that a given market will touch both of two given barrier levels at some point before the expiry of the bet ;

a “win”, “place” or “show” bet that a market will be respectively the best, or within the top two best, or top three best, performing markets (in percentage terms) over a given period ; and

a “quinella”, “tierce” or “exacta” bet defined from their racetrack equivalents.

An example of how the price of an expiry range bet might be calculated is as follows:

The formula for the underlying asset price  $S$  is given by:

$$dS = mSdt + sSdz$$

where  $m$  is the growth rate,  $s$  is the volatility,  $t$  is time and  $z$  is a variable that follows a Wiener process. The variable  $z$  can be understood by considering the changes in the value thereof over small intervals of time. Consider a small interval of time having a duration of  $dt$  and define  $dz$  as the change in  $z$  during  $dt$ . There are two basic properties that  $dz$  must have for  $z$  to be following a Wiener process:

$dz$  must be related to  $dt$  by the equation:

$$\Delta z = \varepsilon \sqrt{\Delta t}$$

where  $\varepsilon$  is a random drawing from a standardized normal distribution (i.e., a normal distribution with a mean of zero and a standard deviation of 1.0), and the values of  $dz$ , for any two different short intervals of time  $dt$ , must be independent.

Solving this equation, we obtain:

$$S(t) = S \exp((m - s^2/2)t + sz(t))$$

where  $S(t)$  is the asset price at time  $t$  and  $S$  is the initial asset price.

Let  $\rho$  be the probability of success of a bet in this model at expiry time  $t$ . The present value of this bet thus becomes:

$$P = \exp(-rt)\rho$$

where  $P$  is the present value (or fair price) of the bet,  $r$  is the interest rate, and  $t$  is the time to maturity. We denote:

$$X_t = \log (S(t)/S)$$

and

$$v = r - g - \frac{\sigma^2}{2}$$

where  $S(t)$  is the asset price at time  $t$ ,  $t$  is the time to maturity,  $S$  is the initial asset price,  $r$  is the interest rate,  $g$  is the dividend rate and  $s$  is the volatility.

Then, the variable  $x$  is defined as

$$x = \frac{X_t - vt}{\sigma \sqrt{t}}$$

and is normally distributed with probability density:

$$f(x) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{x^2}{2}\right)$$

Now, we denote:

$$f(y) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right)$$

and

$$N(x) = \int_{-\infty}^x f(y) dy$$

where  $N(x)$  is the cumulative probability of the normal distribution. Let  $S$  be the initial market price, and let

$$a = \log\left(\frac{U}{S}\right) \quad \text{and} \quad b = \log\left(\frac{D}{S}\right)$$

where  $U$  and  $D$  are the up and down barriers of the bet respectively. The price of the expiry range bet, defined by  $U$  and  $D$ , is then given by:

$$P = e^{-r\tau} \left[ N\left(\frac{a - v\tau}{\sigma\sqrt{\tau}}\right) - N\left(\frac{b - v\tau}{\sigma\sqrt{\tau}}\right) \right]$$

Other formulae for different types of bets may readily be derived by employing the same principles. The type of formula employed is also not essential to the working of the system - many different methods of calculating odds exist, and any of these may be used in the system of the present invention.

Once the price of the bet defined by the bet parameters input by the user is determined, a house mark-up is added and the bet is offered to the user via the user

terminal 3. Since the system operates on real-time values derived from the constantly fluctuating markets, the customer is allowed only a short time in which to decide whether or not to purchase the bet at the calculated price. This time period is, preferably, no more than thirty to sixty seconds, and the offer is withdrawn after this time.

If the user decides to purchase the bet, he or she will be prompted to input a username and password (if these were not input at an earlier stage). This information is verified by the central processing machine 1 and, if it is accepted, will check the credit balance of the user on the accounting system 11. If this reveals that the user has sufficient funds to purchase the bet, the transaction with the user is effected and the bet is recorded on the data storage facility 7.

Each user of the system may, on entering his or her valid username and password, view a list of outstanding bets that he or she has placed on a user terminal 3. In order to provide this list, the central processing machine 1 retrieves information regarding the user's previously placed bets from the data storage facility 7. The central processing machine 1 must, for each previously placed bet, determine whether the bet has: already expired or fulfilled the conditions of the bet so that the user has won the bet; already expired or contravened the conditions of the bet so that the user has lost the bet; or has not yet reached the date or conditions of expiry. The central processing machine 1 derives this information by comparing the bet parameters with both real-time market information and historical market information for the relevant time period obtained via the data feeds 5, 6. The status of each previously placed bet is passed to the user terminal 3 for display to the user. If the user has won any of the bets, the central processing machine 1 instructs the accounting system 11 to credit the user's account accordingly.

The system may also be provided with a facility to offer to buy an unexpired bet back from the user. The price that is offered for a bet is calculated by first determining the value of the bet using similar techniques to those described above, with a house mark-up being included in the price. As described above, the user is given no more than thirty to sixty seconds to decide whether or not to accept the price offered before the offer is withdrawn.

All of the transactions between the central processing machine 1 and the users of

the system may be monitored by an administrator of the system at the management terminal 12. This facility allows the administrator to ensure that the system is running smoothly and that the algorithms and/or models employed by the central processing machine 1 are producing appropriate results.

As a further consideration, the administrator of the system may be concerned about his or her financial exposure and the system may accordingly include means to inform the administrator, in real-time, of the financial exposure via the management terminal 12. This facility allows the administrator to "hedge" in the futures and options markets. There are four types of hedging ratio commonly used, namely the delta, theta, gamma and vega hedging ratios. These ratios, along with the appropriate hedging techniques, are well known in the art.

In an alternative ~~embodiment of the invention~~ embodiment, the E-cash or credit card payment system 9 is replaced by a system that operates with "virtual" or "fantasy" money instead of real funds. In such an embodiment, bettors are allocated an initial amount of "fantasy" money to purchase bets. Successful bettors have the chance to win prizes or other benefits.

As a further consideration, whether or not the payment system comprises real or "fantasy" money, the administrator of the system may wish to track the bettors who are consistently successful at forecasting the direction of the financial markets. The administrator knows that under the assumption of efficient markets, no person may consistently forecast the financial markets, and therefore successful bettors are simply those that have been successful by chance. However, tracking successful bettors may provide useful information for the administrator, such as useful clues for tracking down problems with this ~~embodiment of the invention~~. The administrator may also sell or provide the information comprised of the ongoing bets of the successful bettors, to third parties who may choose to use or rely upon this information on the belief that the successful bettors have a special gift rather than being simply lucky.

The betting system ~~embodying the present invention~~ for calculating the fixed-price odds that may be offered to a prospective bettor is particularly well-suited to bets placed on the financial markets since the calculation of fixed-price odds is sufficiently difficult, time consuming and computationally intensive to make calculation thereof by humans inefficient for all but the largest of bets. The system described herein allows an

administrator of the system to offer reasonable and well-calculated odds in real-time to individual speculators betting small sums of money on an almost unlimited number of eventualities, without the need to employ highly-skilled staff to do so. This service has not been available in the past.

~~In the present specification "comprises" means "includes or consists of" and "comprising" means "including or consisting of".~~

It will be obvious to those having skill in the art that many changes may be made to the details of the above-described ~~embodiment of this invention~~ embodiments without departing from the underlying principles thereof. The scope of the present invention should, therefore, be determined only by the following claims.
